BMI Calculator

This program calculating BMI (Body Mass Index) by dividing a person's weight (in kg) by the square of their height (in m). At the end of the program it will display user's BMI and determine the corresponding category:
Below 18.5 => Underweight
18.5 - 24.9 => Normal Weight
25.0 - 29.9 => Overweight
30.0 and above => Obese

Then program will starting from the first automatically.

Code implementation :
The program was written in Python using Visual Studio Code (VS Code) as the code editor

```
while True:
    weight = int(input("Enter your weight in kg: "))
    height = float(input("Enter your height in meters: "))
    bmi = weight / (height * height)
    print(f"Your BMI is: {bmi}")
    if bmi < 18.5:
        print("You are underweight.")
    elif 18.5 <= bmi < 24.9:
        print("You have a normal weight.")
    elif 25 <= bmi < 29.9:
        print("You are overweight.")
    else:
        print("You are obese.")
```

First, the program evaluates the condition in the if statement. If the BMI value does not meet that condition, the program proceeds to check the subsequent elif conditions. If none of the conditions are satisfied, the else statement is executed.

Example output :

```
Enter your weight in kg: 65
Enter your height in meters: 1.7
Your BMI is: 22.49ur height in meters: 1.7
Enter your weight in kg:
```
